# Binomial option pricing

The  
**binomial option pricing model**  
or  
**Cox-Ross-Rubinstein pricing model**  
assumes that

the price of the underlying asset follows a binomial distribution,  
that is,

the asset price in each period can  
move only up or down by a specified amount.

---

The binomial option pricing model enables us to  
determine the price of an option,  
given the characteristics of the stock or other underlying asset.

**Example 10.1-1** Consider an European call option on the stock of XYZ, with a \$40 strike price and one year expiration. XYZ does not pay dividends and its current price is \$41.

Assume that, in a year, the price can be either \$60 or \$30.

Can one determine the call premium?

(Let the continuously compounded risk free interest rate be 8%.)

## *Law of one price*

Positions that have the same payoff should have the same cost!

---

Two portfolios (positions)

- ▶ Portfolio A: Buy one call option.
- ▶ Portfolio B: Buy  $\Delta \in (0, 1)$  option and borrow  $B$  at the risk-free rate.

These two positions should have the same cost.

## *Law of one price*

Positions that have the same payoff should have the same cost!

---

Two portfolios (positions)

- ▶ Portfolio A: Buy one call option.
- ▶ Portfolio B: Buy  $\Delta \in (0, 1)$  option and borrow  $B$  at the risk-free rate.

These two positions should have the same cost.

More generally, suppose the stock change its value over a period of time  $h$  as

Portfolio A

payoff	$d \times S$	$u \times S$
	0	$u \times S - K$
Total	$C_d = 0$	$C_u = u \cdot S - K$

Portfolio B

payoff	$d \times S$	$u \times S$
$\Delta$ share	$\Delta \cdot d \cdot S \cdot e^{\delta h}$	$\Delta \cdot u \cdot S \cdot e^{\delta h}$
$B$ bond	$Be^{rh}$	$Be^{rh}$
Total	$\Delta \cdot d \cdot S \cdot e^{\delta h} + Be^{rh}$	$\Delta \cdot u \cdot S \cdot e^{\delta h} + Be^{rh}$

For two unknowns:  $\Delta$  and  $B$ , solve:

$$\begin{cases} \Delta dSe^{\delta h} + Be^{rh} = C_d \\ \Delta uSe^{\delta h} + Be^{rh} = C_u \end{cases}$$

---

Set  $S_h$  be either  $dS$  or  $uS$  and

$C_h$  be either  $C_u$  or  $C_d$ .

Plot  $S_h$  (x-axis) versus  $C_h$  (y-axis).

$$\Delta S_h e^{\delta h} + Be^{rh} = C_h$$

$$\Delta = e^{-\delta h} \frac{C_h - C_d}{S(u - d)} \quad \text{and} \quad B = e^{-rh} \frac{uC_d - dC_u}{u - d}$$

$$\Delta S + B = e^{-rh} \left( C_u \underbrace{\frac{e^{(r-\delta)h} - d}{u - d}}_{:=p^*} + C_d \underbrace{\frac{u - e^{(r-\delta)h}}{u - d}}_{:=1-p^*} \right)$$

$p^*$  the **risk-neutral probability** of  
an increase in the stock price.

## Arbitraging a mispriced option

**Example 10.1-2** Find arbitrage opportunities in Example 10.1-1 with

- ▶ the option price being overpriced with \$9.00;
- ▶ the option price being underpriced with \$8.25,

instead of the risk-neutral pricing \$8.871.

## Arbitraging a mispriced option

**Example 10.1-2** Find arbitrage opportunities in Example 10.1-1 with

- ▶ the option price being overpriced with \$9.00;
- ▶ the option price being underpriced with \$8.25,

instead of the risk-neutral pricing \$8.871.

## Arbitraging a mispriced option

**Example 10.1-2** Find arbitrage opportunities in Example 10.1-1 with

- ▶ the option price being overpriced with \$9.00;
- ▶ the option price being underpriced with \$8.25,

instead of the risk-neutral pricing \$8.871.

## Arbitraging a mispriced option

**Example 10.1-2** Find arbitrage opportunities in Example 10.1-1 with

- ▶ the option price being overpriced with \$9.00;
- ▶ the option price being underpriced with \$8.25,

instead of the risk-neutral pricing \$8.871.
