Chapter 9. Parity and other option relationships

Chapter 9. Parity and other option relationships

§ 9.1 Put-call parity

§ 9.2 Generalized parity and exchange options

§ 9.3 Comparing options with respect to style, maturity, and strike

§ 9.4 Problems

Chapter 9. Parity and other option relationships

§ 9.1 Put-call parity

§ 9.2 Generalized parity and exchange options

§ 9.3 Comparing options with respect to style, maturity, and strike

§ 9.4 Problems

European options

$$C(K,T) - P(K,T) = PV_{0,T}(F_{0,T} - K)$$
$$= e^{-rT}(F_{0,T} - K)$$

Buying a call and selling a put with the strike both equal to the forward price (i.e., $K = F_{0,T}$ creates a synthetic forward contract and hence must have a zero price.

Parity generally fails for American options!

European options

$$C(K,T) - P(K,T) = PV_{0,T}(F_{0,T} - K)$$
$$= e^{-rT}(F_{0,T} - K)$$

Buying a call and selling a put with the strike both equal to the forward price (i.e., $K = F_{0,7}$) creates a synthetic forward contract and hence must have a zero price.

Parity generally fails for American options!

European options

$$C(K,T) - P(K,T) = PV_{0,T}(F_{0,T} - K)$$
$$= e^{-rT}(F_{0,T} - K)$$

Buying a call and selling a put with the strike both equal to the forward price (i.e., $K = F_{0,T}$) creates a synthetic forward contract and hence must have a zero price.

Parity generally fails for American options!

Parity for stocks

$$C(K,T) = P(K,T) + (S_0 - PV_{0,T}(Div)) - e^{-rT}K$$

Example 9.1-1 Suppose that the price of a non-dividend-paying stock is \$40, the continuously compounded interest rate is 8%, and options have 3 months to expiration. If a 40-strike European call sells for \$2.78, find the price for a 40-strike European put sells.

Solution. Let the price for put be *y*. Then

$$\$2.78 = y + \$40 - \$40e^{-0.08 \times 0.25}$$

Hence.

$$y = \$1.99$$

Example 9.1-1 Suppose that the price of a non-dividend-paying stock is \$40, the continuously compounded interest rate is 8%, and options have 3 months to expiration. If a 40-strike European call sells for \$2.78, find the price for a 40-strike European put sells.

Solution. Let the price for put be *y*. Then

$$$2.78 = y + $40 - $40e^{-0.08 \times 0.25}$$

Hence,

$$y = $1.99.$$

Why is a call more expensive than a put?

When $S_0 = K$ and Div = 0, then

$$C(K,T) - P(K,T) = K\left(1 - e^{-rT}\right)$$

The difference of a call and put is the time value of money.

Why is a call more expensive than a put?

When $S_0 = K$ and Div = 0, then

$$C(K,T) - P(K,T) = K\left(1 - e^{-rT}\right)$$

The difference of a call and put is the time value of money.

Why is a call more expensive than a put?

When $S_0 = K$ and Div = 0, then

$$C(K,T) - P(K,T) = K\left(1 - e^{-rT}\right)$$

The difference of a call and put is the time value of money.

Example 9.1-2 Make the same assumptions as in Example 9.1-1, except suppose that the stock pays a \$5 dividend just before expiration. If the price of the European call is \$0.74, what would be the price of the European put?

Solution. Let the price for put be y. Then

$$\$0.74 = y + (\$40 - \$5e^{-0.08 \times 0.25}) - \$40e^{-0.08 \times 0.25}$$

Hence,

$$y = $4.85$$

Example 9.1-2 Make the same assumptions as in Example 9.1-1, except suppose that the stock pays a \$5 dividend just before expiration. If the price of the European call is \$0.74, what would be the price of the European put?

Solution. Let the price for put be *y*. Then

$$\$0.74 = \mathbf{y} + (\$40 - \$5\mathbf{e}^{-0.08 \times 0.25}) - \$40\mathbf{e}^{-0.08 \times 0.25}$$

Hence,

$$y = $4.85.$$

Q

Synthetic securities

$$C(K,T) = P(K,T) + (S_0 - PV_{0,T}(Div)) - e^{-rT}K$$

► Synthetic stock

$$S_0 = C(K, T) - P(K, T) + PV_{0,T}(Div) + e^{-rT}K$$

$$C(K,T) = P(K,T) + (S_0 - PV_{0,T}(Div)) - e^{-rT}K$$

$$\underbrace{S_0 - C(K, T) + P(K, T)}_{\text{a conversion}} = \text{PV}_{0, T}(\text{Div}) + e^{-rT}K$$

Motivation

A hedged position that has no risk but requires investment T-bills are taxed differently than stocks.

$$C(K,T) = P(K,T) + (S_0 - PV_{0,T}(Div)) - e^{-rT}K$$

$$\underbrace{S_0 - C(K, T) + P(K, T)}_{\text{a conversion}} = \text{PV}_{0, T}(\text{Div}) + e^{-rT}K$$

Motivation:

A hedged position that has no risk but requires investment T-bills are taxed differently than stocks.

$$C(K,T) = P(K,T) + (S_0 - PV_{0,T}(Div)) - e^{-rT}K$$

$$\underbrace{S_0 - C(K, T) + P(K, T)}_{\text{a conversion}} = \text{PV}_{0, T}(\text{Div}) + e^{-rT}K$$

Motivation:

A hedged position that has no risk but requires investment.

T-bills are taxed differently than stocks

$$C(K,T) = P(K,T) + (S_0 - PV_{0,T}(Div)) - e^{-rT}K$$

$$\underbrace{S_0 - C(K, T) + P(K, T)}_{\text{a conversion}} = \text{PV}_{0, T}(\text{Div}) + e^{-rT}K$$

Motivation:

A hedged position that has no risk but requires investment. T-bills are taxed differently than stocks.

Synthetic securities

$$C(K,T) = P(K,T) + (S_0 - PV_{0,T}(Div)) - e^{-rT}K$$

Synthetic options

$$C(K,T) = P(K,T) + (S_0 - PV_{0,T}(Div)) - e^{-rT}K$$

$$P(K, T) = C(K, T) - (S_0 - PV_{0,T}(Div)) + e^{-rT}K$$
