# What happens to the option price when one and only one input changes?

- ▶ Delta ( $\Delta$ ): change in option price when stock price increases by \$1
- ▶ Gamma ( $\Gamma$ ): change in delta when option price increases by \$1
- ightharpoonup Vega: change in option price when volatility increases by 1%
- ▶ Theta  $(\theta)$ : change in option price when time to maturity decreases by 1 day
- $\triangleright$  Rho ( $\rho$ ): change in option price when interest rate increases by 1%
- ▶ Psi  $(\psi)$ : change in the option premium due to a change in the dividend vield

➤ The Greek measure of a portfolio is weighted average of Greeks of individual portfolio components

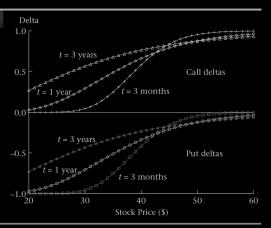

$$\Delta_{\text{portfolio}} = \sum_{i=1}^{N} n_i \Delta_i$$

## Delta

Delta  $(\Delta)$ : change in option price when stock price increases by \$1.

$$\Delta = \begin{cases} \frac{\partial C(S, K, \sigma, T - t, \delta)}{\partial S} = +e^{-\delta(T - t)}N(+d_1) & \text{Call} \\ \frac{\partial P(S, K, \sigma, T - t, \delta)}{\partial S} = -e^{-\delta(T - t)}N(-d_1) & \text{Put} \end{cases}$$

Call (top graph) and put (bottom graph) deltas for 40-strike options with different times to expiration. Assumes  $\sigma=30\%,\ r=8\%,\$ and  $\delta=0.$ 

# Gamma and Vega

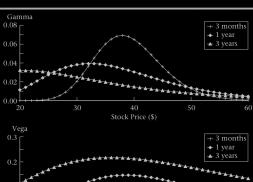

Gamma ( $\Gamma$ ): change in delta when option price increases by \$1

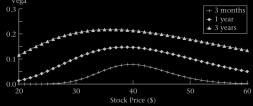

$$\Gamma = \frac{\partial^2 \textit{C}(\textit{S},\textit{K},\sigma,\textit{r},\textit{T}-\textit{t},\delta)}{\partial \textit{S}^2} = \frac{\partial^2 \textit{P}(\textit{S},\textit{K},\sigma,\textit{r},\textit{T}-\textit{t},\delta)}{\partial \textit{S}^2} = \frac{\textit{e}^{-\textit{d}(\textit{T}-\textit{t})\textit{N}'(\textit{d}_1)}}{\textit{S}\sigma\sqrt{\textit{T}-\textit{t}}}$$

Vega: change in option price when volatility increases by 1%

$$\mathrm{Vega} = \frac{\partial \textit{\textbf{C}}(\textit{\textbf{S}}, \textit{\textbf{K}}, \sigma, \textit{\textbf{r}}, \textit{\textbf{T}} - \textit{\textbf{t}}, \delta)}{\partial \sigma} = \frac{\partial \textit{\textbf{P}}(\textit{\textbf{S}}, \textit{\textbf{K}}, \sigma, \textit{\textbf{r}}, \textit{\textbf{T}} - \textit{\textbf{t}}, \delta)}{\partial \sigma} = \textit{\textbf{Se}}^{-\delta(T-t)} \textit{\textbf{N}}'(\textit{\textbf{d}}_1) \sqrt{T - \textit{\textbf{t}}}$$

Gamma (top panel) and vega (bottom panel) for 40strike options with different times to expiration. Assumes  $\sigma = 30\%, r = 8\%, \text{ and }$  $\delta = 0$ . Vega is the sensitivity of the option price to a 1 percentage point change in volatility. Otherwise identical calls and puts have the same gamma and vega.

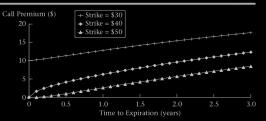

# Theta

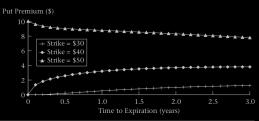

Theta  $(\theta)$ : change in option price when time to maturity decreases by 1 day

$$\begin{aligned} \operatorname{Call} \, \theta &= \frac{\partial C(S,K,\sigma,r,T-t,\delta)}{\partial t} \\ &= \delta S e^{-\delta(T-t)} N(d_1) - r K e^{-r(T-t)} N(d_2) - \frac{K e^{r(T-r)} N'(d_2) \sigma}{2 \sqrt{T-t}} \end{aligned}$$

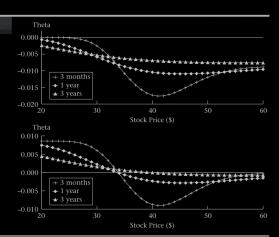

$$\operatorname{Put} \, \theta &= \frac{\partial P(S,K,\sigma,r,T-t,\delta)}{\partial t} \\ &= \operatorname{Call} \, \theta + r K e^{-r(T-t)} + \delta S e^{-\delta(T-t)} \end{aligned}$$

Call (top panel) and put (bottom panel) prices for options with different strikes at different times to expiration. Assumes  $S=\$40, \sigma=30\%, r=8\%,$  and  $\delta=0.$ 

Theta for calls (top panel) and puts (bottom panel) with different expirations at different stock prices. Assumes K=\$40,  $\sigma=30\%$ , r=8%, and  $\delta=0$ .

# Rho and Psi

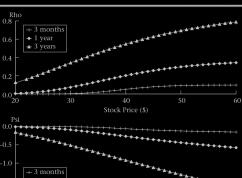

Rho  $(\rho)$ : change in option price when interest rate increases by 1%

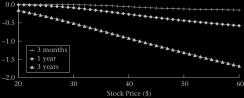

$$\begin{aligned} & \text{Call } \rho = \frac{\partial \textit{C}(\textit{S}, \textit{K}, \sigma, \textit{r}, \textit{T} - \textit{t}, \delta)}{\partial \textit{r}} = + (\textit{T} - \textit{t})\textit{K}\textit{e}^{-\textit{r}(\textit{T} - \textit{t})}\textit{N}(+\textit{d}_2) \\ & \text{Put } \rho = \frac{\partial \textit{P}(\textit{S}, \textit{K}, \sigma, \textit{r}, \textit{T} - \textit{t}, \delta)}{\partial \textit{r}} = - (\textit{T} - \textit{t})\textit{K}\textit{e}^{-\textit{r}(\textit{T} - \textit{t})}\textit{N}(-\textit{d}_2) \end{aligned}$$

Psi  $(\psi)$ : change in the option premium due to a change in the dividend yield

$$\begin{aligned} \operatorname{Call} \ \psi &= \frac{\partial \textit{C}(\textit{S}, \textit{K}, \sigma, \textit{r}, \textit{T} - \textit{t}, \delta)}{\partial \delta} = -(\textit{T} - \textit{t})\textit{Ke}^{-\delta(\textit{T} - \textit{t})}\textit{N}(+\textit{d}_1) \\ \operatorname{Put} \ \psi &= \frac{\partial \textit{P}(\textit{S}, \textit{K}, \sigma, \textit{r}, \textit{T} - \textit{t}, \delta)}{\partial \delta} = +(\textit{T} - \textit{t})\textit{Ke}^{-\delta(\textit{T} - \textit{t})}\textit{N}(-\textit{d}_1) \end{aligned}$$

Rho (top panel) and psi (bottom panel) at different stock prices for call options with different maturities. Assumes K = \$40,  $\sigma =$ 30%, r = 8%, and  $\delta = 0$ .

### TABLE 12.1

Binomial option prices for different numbers of binomial steps. As in Figure 10.3, all calculations assume that the stock price S = \$41, the strike price K = \$40, volatility  $\sigma = 0.30$ , risk-free rate r = 0.08, time to expiration T = 1, and dividend yield  $\delta = 0$ .

Number of Steps (n) Binomial Call Pri	ce (\$)
1 7.839	
4 7.160	
10 7.065	
50 6.969	
100 6.966	
500 6.960	
$\infty$ 6.961	

Delta ( $\Delta$ ): change in option price when stock price increases by \$1

Option Elasticity ( $\Omega$ ): If stock price S changes by 1%, what is the percentage change in the value of the option C:

$$\Omega = \frac{\text{Percentage change in option price}}{\text{Percentage change in stock price}} = \frac{\frac{\epsilon \Delta}{C}}{\frac{\epsilon}{S}} = \frac{S\Delta}{C}.$$
